# PROGNOSTIC VALUE OF THE DENSITY OF TUMOR-INFILTRATING LYMPHOCYTES AND ITS ASSOCIATION WITH CLINICAL-MORPHOLOGICAL FEATURES OF COLON ADENOCARCINOMAS

**Aim**. To study the prognostic value of the density of tumor-infiltrating lymphocytes (TILs) and its association with other clinical-morphological parameters in colon adenocarcinomas (CAC). **Materials and Methods**. 236 CAC samples were examined. TILs density was estimated as the percentage of tumor stromal area occupied by TILs. By the index of TILs density, the patients were divided into 3 groups: TILs 0—9% (n = 88); TILs 10—39% (n = 106); TILs > 40% (n = 42). Dependent on this index, their overall survival (OS) was analyzed. **Results**. Kaplan — Meier curves revealed a significant (p < 0.001) difference in the OS for patients with different TILs infiltration intensities. Multivariate Cox's proportional hazard regression model analysis has confirmed that patients with moderate TILs density (HR 0.57, 95% CI 0.34—0.96, p = 0.035) had better OS rates compared to low TILs density. TILs were associated with the stage (p < 0.001), lymph node metastasis pN (p < 0.001), distant metastasis M (p < 0.001), and the patient's outcome (p < 0.001). **Conclusion**. TILs can be considered an additional prognostic tool during regular histological examination and are strongly associated with the most significant clinical-morphological features of CAC.

Keywords: tumor-infiltrating lymphocytes, colon cancer, overall survival, prognosis, adenocarcinoma.

Colorectal cancer (CRC) is a burden on the health care system, being the second leading cause of cancer-related death and causing a steady increase in the annual incidence of cancer [1, 2]. Such an increase is closely related to the "western lifestyle". The greatest increase in morbidity and mortality is observed in low- and middle-income countries. In well-developed countries, the stabilization and reduction of morbidity and mortality trends are noted, in strict correlation with the

available preventive measures [3]. Enhancement of diagnostic procedures and tumor features assessment can improve overall patient outcomes, so the search for additional prognostic instruments is still actual [4—6].

Most mutations that occur in sporadic CTC usually follow the DNA mismatch repair pathway (MMR) [7]. FDA has approved Nivolumab with low-dose ipilimumab as a first-line immunotherapy for MSI-high/MMR-deficient metastatic CRC [8].

Despite the clinical decision-making value of the MMR status, there are still gaps in prognostication for CRC patient outcomes. Tumorinfiltrating lymphocytes (TILs) can be utilized as an additional strong prognostic factor for treatment response and overall survival (OS) of CRC patients [9, 10]. TILs can be easily calculated during the regular diagnosis assessment by pathologists. The methodology of TILs count does not require any additional cost as it is done on regular hematoxylin-eosin (H&E) slides.

## **Materials and Methods**

236 formalin fixed paraffin embedded tumor samples from colon adenocarcinoma (CAC) resections were used for this study.

The study was approved by the Commission on Bioethical Expertise (expert conclusion No. 118 from 18.01.2019).

The tumor histological type and grade were accessed based on the 5<sup>th</sup> edition of the WHO classification of tumors of digestive system 2019 [11]. For scoring the tumor to stroma ratio (TSR), we used the recommendations proposed by Pelt et al. [12].

The calculation of TILs density was based on the recommendations of the International Working Group on TILs evaluation in breast cancer [13]. Only lymphocytes that are situated in tumor stroma must be considered part of TILs. The calculation should not include granulocytes. The TILs density is considered as a percentage of lymphocytes compared to the amount of stroma component. For the following statistical calculations, patients were divided into 3 groups dependent on the TILs density: group A, TILs 0—9%; group B, TILs 10—39%; and group C, TILs 40—100%.

All samples were examined by two independent pathologists to determine the level of agreement in TILs evaluation. Both pathologists were provided with the same recommendations described above and were blinded to any patient's clinical data.

For statistical analysis, we used an EZR 1.35 software package (R statistical software version 3.4.3. R Foundation for Statistical Computing, Vienna, Austria) [14]. The Kaplan — Meier method with a log-rank test was used to analyze survival data. OS rates were calculated by the univariate and multivariate Cox's proportional hazard regression models. The chi-square test was used

for estimation of association between significant prognostic factors. To determine the consistency between pathologists, the Kappa Cohen coefficient (k) was used. k < 0.20 was considered as a poor level of agreement; k = 0.21 - 0.41 – fair; k = 0.41 - 0.61 – moderate; k = 0.61 - 0.81 – high; and k > 0.81 – almost perfect. p-values less than 0.05 were considered significant.

### Results

We analyzed 236 cases of CAC. The mean overall survival (OS) period was 3.2 years (range 0.08—7.3 years). The main clinical and pathological characteristics of the CAC cases are presented in Table 1.

Based on the percentage of lymphocytic infiltrate, all the CAC samples were divided into the following groups: group A — no lymphocytic infiltration or a small number of TILs, n = 88; group B — with a moderate number of TILs, n = 106; and group C — with a high lymphocytic infiltration, n = 42 (Figs. 1—3).

The one-year OS in patients with CAC was  $87.2 \pm 2.1\%$ ; 2-year OS was  $78.2 \pm 2.6\%$ ; 3-year OS was  $72.0 \pm 2.9\%$ , and in group A these indices were  $79.3 \pm 4.3\%$ ;  $66.6 \pm 5.0\%$ ; and  $58.0 \pm 5.3\%$ , respectively; in group B —  $89.6 \pm 2.9\%$ ;  $84.9 \pm 3.4\%$ ; and  $78.5 \pm 4.0\%$ , respectively; and in group C 1-year OS and 2-year OS were  $90.5 \pm 4.5\%$  and  $85.6 \pm 5.4\%$ , respectively.

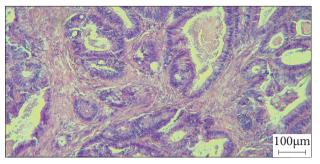

The Kaplan — Meier curves showed that the differences in OS between groups A, B, and C were statistically significant (p < 0.001 by log-rank test) (Fig. 4).

Using univariant Cox's proportional hazard regression model, we showed that OS rates in the group A were significantly lower compared to groups B and C (p = 0.001 and 0.001, respectively) (Table 2). Also, the tumor stage (p < 0.001), presence of metastases in lymph nodes pN (p < 0.001), presence of distant metastases M (p < 0.001), and tumor stroma TSR (p < 0.001) showed a statistically significant influence on OS (Table 2).

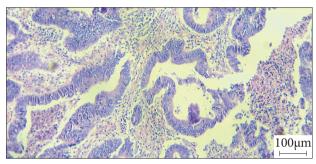

However, multivariate Cox's proportional hazard regression model analysis using Akaike's Information Criterion (AIC) for stepwise selection of the most significant prognostic features revealed that TILs density (p = 0.039), TSR (p = 0.019), and the presence of metastases in lymph nodes pN (p < 0.001) have the greatest impact on the OS of CAC patients (Table 3).

So based on these data, TILs density can be considered an independent prognostic factor.

Based on the analysis of the relationship between clinical-morphological parameters and TILs, we revealed that the TILs density was associated with the stage (p < 0.001), presence of lymph

node metastases pN (p < 0.001), presence of distant metastases M (p < 0.001), and the outcome (p < 0.001). There was no statistically significant relationship between TILs density and histological tumor type, grade, depth of invasion pT, TSR, presence of necrosis, and tumor budding (Table 4).

|                       | Overall survival |  |         |  |
|-----------------------|------------------|--|---------|--|
| Parameter             | Hazard ratio     | Relative risk with 95% confidence interval | p       |  |
| TILs density          |                  |  | 0.039   |  |
| Group A (0—9%)        | Referent         |  |         |  |
| Group B (10—39%)      | 0.57             | 0.34—0.96                                  | 0.035   |  |
| Group C (>40%)        | 0.41             | 0.17—1.01                                  | 0.054   |  |
| Tumor-to-stroma ratio |                  |  |         |  |

| pN2                   | 4.26             | 2.17—8.34                                  | < 0.001 |  |

Table 3. Multivariate Cox regression analysis of factors predicting OS of CAC patients

The TILs density was equally scored in 199 of 236 cases by both pathologists, and the overall agreement was 86%. The expected frequency of the agreements that would have been expected by chance was calculated by Pearson's Chi-squared test: it was equal to 31.32 for group A (TILs 0—9%); 48.05 for group B (TILs 10%—39%); and 8.02 for group C (TILs > 40%). The Kappa Cohen coefficient (0.75) demonstrated a high level of the agreement between pathologists scoring TILs.

## Discussion

Despite the progress in the understanding of CAC development, surgery is a basic treatment option, and the administration of chemotherapy is still majorly based on TNM [15—18].

Nowadays, the tumor microenvironment (TME) is considered one of the keys to the mechanisms of tumor origin, development, progression, and interaction with the host [19]. The major TME compartments are tumor stroma and tumor immune infiltrate, which include tumor-associated macrophages, tumor-associated neutrophils, and TILs [20, 21]. The numerous studies support the prognostic value of TSR for patient's outcome. TSR-rich triple-negative breast carcinomas and colon carcinomas have better overall and diseasefree survival. Additionally, statistical data confirm that TSR can be considered an independent prognostic marker for breast cancer [23, 24]. In gall bladder tumors, TSR has also been confirmed to have a prognostic significance but cannot be utilized as an independent tool [24]. TSR did not show any prognostic value in pancreatic ductal adenocarcinoma [25].

Lymphocytes play a leading role in antitumor immune reactions. Several studies specifically showed that B-cells perceive tumor antigens and produce antitumor antibodies assisting T-helper cells in tumor recognition. CD8+ T-cells directly lyse the tumor cells. On the other hand, CD4+ T-cells (Treg) are responsible for tumor immune tolerance by effector T-cell suppression [26, 27]. Naito et al. [28] showed that the higher number of CD8+ T-cells, the better patients' outcomes and suggested to utilize it as a prognostic factor. Also, CD8+ T-cells showed prognostic significance in endometrial and lung cancer [29, 30]. Lymphocyte population distinction with IHC gives more possibilities for precise lymphocyte calculation and allows us to make sure that other immune cells are excluded. However, the procedure requires additional tissue processing, which takes time and increases the cost of diagnostics.

Yet, in the current study we aimed to investigate the potential of TILs detection in general, without division into subpopulations. The advantage of such TILs count is their calculation on regular H&E-stained slides during routine diagnostics without additional expenses.

The TILs density showed its utility as a prognostic tool in triple-negative breast cancer. The high number of TILs is associated with the better OS [31, 32]. The calculation methodology we used had been proposed by the International TILs

Table 4. Association of TILs density with other clinical-morphological parameters in colorectal adenocarcinomaCAC

| Parameter                           | Group A (mean age 63.0) |              | Group B (mean age 65.6) |              | Group C<br>(mean age 67.8) |              | p       |
|-------------------------------------|-------------------------|--------------|-------------------------|--------------|----------------------------|--------------|---------|

Working Group 2014 [13]. A high level of the agreement between pathologists confirms a good reproducibility of the method. In our study, the Kappa coefficient was 0.75. There are other methodologies that confirm the prognostic value of TILs. Dülgar et al. [33] divided tumors due to TILs density into group 0 without lymphocytic infiltrate, group 1+ with low TILs number

(<30%), group 2+ (with moderate TILs count (30%—60%), and group 3+ with more than 60% of TILs. The variations of methodologies that can be utilized during the TILs calculations mean that there is a need for standardization. However, the fact that the TILs density shows a prognostic value regardless the calculation method confirms its hidden potential.

Unfortunately, in our research, we had limited data on OS in group C with the highest TILs intensity (just 2-year OS). Our study has several other limitations. It is a retrospective study that included patients treated in 2012—2020. During this period, treatment strategies have varied by treatment protocols, as well as by the number of chemotherapy cycles.

In conclusion, our study has shown a prognostic significance of TILs density for OS in patients with CAC. Due to simplicity, assessment of TILs density can be carried out during regular histological examinations. The association of TILs density with other prognostically significant clinical features testi-

fies in favor of its major importance in CAC progression. The extended studies of TILs can help develop precise treatment strategies for CRC patients.

ПРОГНОСТИЧНЕ ЗНАЧЕННЯ ПУХЛИНО-ІНФІЛЬТРУЮЧИХ ЛІМФОЦИТІВ ТА ЇХ ЗВ'ЯЗОК З КЛІНІКО-МОРФОЛОГІЧНИМИ ХАРАКТЕРИСТИКАМИ АДЕНОКАРЦИНОМИ ТОВСТОЇ КИШКИ

**Мета дослідження**: вивчити прогностичне значення пухлино-інфільтруючих лімфоцитів (ПІЛ) та їх зв'язок з клініко-морфологічними параметрами при аденокарциномах товстої кишки. **Матеріали та методи**: для цього дослідження було використано 236 зразків аденокарциноми товстої кишки. ПІЛ оцінювали як відсоток площі строми пухлини, яка була зайнята ПІЛ. За інтенсивністю інфільтрації ПІЛ пацієнтів було розділено на 3 групи: ПІЛ 0—9% (n = 88); ПІЛ 10—39% (n = 106); ПІЛ > 40% (n = 42). **Результати**. На основі кривої виживаності Каплана — Мейєра існує статистично значуща (p < 0,001) різниця в загальній виживаності для пацієнтів з різною інтенсивністю ПІЛ. Аналіз моделі пропорційних ризиків Кокса підтверджує, що ПІЛ має статистично значущий вплив на загальну виживаність. Пацієнти з помірним ПІЛ (HR 0,57, 95%; СІ 0,34—0,96, p = 0,035) мають кращі загальні показники виживаності порівняно з групою з низьким відсотком ПІЛ. ПІЛ пов'язані зі стадією (p < 0,001), метастазами в лімфатичних вузлах рN (p < 0,001), віддаленими метастазами М (p < 0,001) і виживаністю (p < 0,001). **Висновки**. ПІЛ можна розглядати як додатковий прогностичний інструмент під час звичайного гістологічного дослідження. Він має сильний зв'язок із впливовими клініко-морфологічними ознаками.

**Ключові слова:** пухлино-інфільтруючі лімфоцити, рак товстої кишки, загальна виживаність, прогноз, аденокарцинома.
