**ANTIPROLIFERATIVE AND APOPTOTIC EFFECT OF ETHANOLIC EXTRACT OF CALOCYBE INDICA ON PANC-1 AND MIAPaCa2 CELL LINES OF PANCREATIC CANCER**

*S.K. Ghosh*, T. Sanyal

Cancer Research Unit, PG Department of Botany, Ramakrishna Mission Vivekananda Centenary College, Rahara, Kolkata 700118, India

Background: Pancreatic cancer is an aggressive malignancy with poor prognosis. New options for its treatment including the use of the substances of natural origin are now on the agenda. Aim: An attempt has been taken to examine the effect of ethanolic extract (EE) of edible mushroom *Calocybe indica* on PANC-1 and MIAPaCa2 cell lines of pancreatic cancer in vitro. Materials and Methods: Study of cell morphology, evaluation of apoptosis by DAPI staining under fluorescence microscope, anti-proliferative study by MTT assay, lactate dehydrogenase assay, pro-apoptotic and anti-apoptotic protein detection by Western blotting were performed to test effects of *Calocybe indica* EE on the cells of these two lines. Effect on in vitro migration was studied by scratch method. Results: Both cell lines treated with 250 or 500 µg/mL of EE underwent morphological changes — became more round and shrunken, with membrane blebbing and the reduced cell confluence. The nuclei of treated cells became condensed and fragmented. The percentage of apoptotic cells increased as EE concentration increased from 100 µg/mL to 500 µg/mL. Anti-proliferative effect was recorded at all concentrations within 100–750 µg/mL. The effect EE on lactate dehydrogenase leakage was concentration-dependent in both cell lines. Western blotting showed that caspase-3 and -9, and p53 protein levels were increased and Bcl2 protein was decreased after treatment of the cells with EE compared to the control. PANC-1 cell migration was inhibited by 80.12 ± 4.25% after 24 h treatment of the cells with 500 µg/mL EE compared to the control. Conclusions: EE of *Calocybe indica* inhibits the growth and induces apoptosis in pancreatic cancer cell lines in vitro.

Key Words: ethanolic extract, anticancer agent, PANC-1, MIAPaCa2, apoptosis, cytotoxicity.

DOI: 10.32471/exp-oncology.2312-8852.vol-42-no-3.15086

Pancreatic cancer is one of the leading causes of cancer death worldwide, with 232,000 new cases and 213,000 deaths reported each year. Pancreatic cancer is the fourth leading cause of cancer-related deaths in the United States. Although pancreatic cancer is relatively common in Western countries, the epidemiological data demonstrated that the incidence of pancreatic cancer is 0.5–2.4 per 100,000 men and 0.2–1.8 per 100,000 women in most parts of India [1]. As per the data of Cancer Facts and Figures 2019 [2], the incidence rate of pancreatic cancer increases about 1% per year, and the survival rate is very poor (5–6%) in the first 5 years. As pancreatic cancer shows no symptoms, its early detection and diagnosis is not possible [3]. Moreover, due to its very rapid growth, spreading to distant organs, and resistance to most therapies, the management of this cancer is now extremely challenging.

Gemcitabine has been used as standard chemotherapy for pancreatic cancer [4], but most clinical trials have failed to demonstrate markedly improved oncologic outcomes [5]. Folfirinox is an emerging chemotherapeutic agent for metastatic pancreatic cancer treatment [6]. Scientists are now engaged in searching for formulation of new drugs from natural products of plants, bacteria, fungi, animals or other sources. Cancer myotherapy is an emerging medical field, which deals with anticancer agents originated from mushrooms. More than 50 mushroom species have already exhibited potential anticancer activity in vitro or in animal models and six substances have been tested clinically [7].

*Calocybe indica* is a mushroom commonly grown in wild and cultivated in West Bengal province of India. Earlier, we demonstrated anticancer effect of *Calocybe indica* extract in breast cancer and Ewing’s sarcoma cell lines [8]. Although the antiproliferative activity of the extracts from a few mushrooms has been assayed in human pancreatic cancer cells [9, 10], *Calocybe indica* extract has not been yet studied for this purpose. Therefore, an attempt has been taken to examine the effect of ethanolic extract (EE) of edible mushroom *Calocybe indica* on PANC-1 and MIAPaCa2 cell lines of pancreatic cancer in vitro.

**MATERIALS AND METHODS**

*Mushroom collection and extraction.* The cultivated basidiocarps of *Calocybe indica* were collected in July 2018 from Rahara market, District-24-Parganas (S), India and carried to laboratory for their identification. The young fruit bodies of the mushroom whose caps were unopened were air dried in oven at 50 °C for 48 h, chopped into pieces and then grinded into powder. 15 g of dried mushroom powder was extracted for 3 days in 150 mL of 90% ethanol at room temperature and filtered through Whatman № 4 and Whatman № 1. The ethanol was removed from the extract using a rotary vacuum evaporator at 40 °C, and the remaining solvent was removed with a freeze-drier. The powder of EE of *C. indica* was kept in airtight condition in refrigerator at 4 °C. Extract

Abbreviations used: DAPI – 4',6-diamidino-2-phenylindole; EE – ethanolic extract; LDH – lactate dehydrogenase; PBS – phosphate buffered saline.
used for in vitro assays was dissolved in Roswell Park Memorial Institute 1640 medium and passed through a 0.22 μm Millipore filter. The prepared EE was further diluted with plain Roswell Park Memorial Institute 1640 medium to certain concentrations just prior to use. The yield of EE of C. indica was 3.65 (w/w).

Cell culture. The human pancreatic cancer cell lines (PANC-1 and MIAPaCa2) (purchased from NCCS, Pune) were cultured separately in DMEM supplemented with L-glutamine, 10% v/v fetal bovine serum 100 μg/mL streptomycin (Invitrogen, USA) and 250 IU/mL penicillin (Invitrogen, USA), in 75 mm² tissue culture flasks at 37 °C in a humidified atmosphere of 5% CO₂ to the 60–70% confluence. Cells were treated with EE (0–500 μg/mL) and then examined under bright field inverted microscope.

Nuclear morphology and apoptosis evaluation by DAPI staining. 4’,6-diamidino-2-phenylindole (DAPI) stain was used to observe nuclear morphology of cells. The cells were washed by cold phosphate-buffered saline (PBS) and fixed with 3.7% (w/v) formaldehyde in PBS for 10 min at room temperature. After permeabilization, the cells were stained with a DAPI solution (10 μg/mL) at 37 °C for 30 min. The stained cells were washed with PBS and observed using an inverted fluorescent microscope (Olympus, Japan), photographs were taken using a Magna-Fire digital camera (Optotronics, USA) for analysis. Apoptosis was evaluated by morphological changes of the nuclear structure. The apoptotic cells were observed and counted under an inverted fluorescent microscope; at least five optical fields were counted containing a total of 200 cells. The percentage of apoptotic cells was calculated by the formula:

\[
\text{percentage of apoptotic cells} = \left( \frac{\text{number of apoptotic cells}}{\text{total cells counted}} \right) \times 100\%
\]

Cell proliferation/cytotoxicity assay. The effects of EE on cell proliferation of PANC-1 and MIAPaCa2 cell lines were evaluated by using dimethyl thiazolyl tetrazolium bromide (MTT) assay (Sigma, USA) following the method of Mosmann [11] with some modification. Briefly, 1 × 10⁴ cells per well of 96-well culture plate were seeded in fresh DMEM medium, containing 10% FBS and antibiotics, overnight to reach 80% confluence. Then the culture was washed with 100 μL PBS and treated with different concentrations of EE dissolved in DMEM and incubated at 37 °C in 5% of CO₂ and 95% of air for 24 h. Upon incubation, cells were washed with PBS, and 100 μL of 0.5% MTT solution in Roswell Park Memorial Institute 1640 was added to each well and cultures were further incubated for 3 h, then after discarding the media, 100 μL of DMSO was added for dissolving the crystals. The absorbance in the wells was measured in microplate reader (Bio Rad, USA) at 570 nm.

Growth inhibition rate was determined by the formula:

\[
\text{Growth inhibition} = \left( \frac{A \text{ 570 nm treated cells}}{A \text{ 570 nm control cells}} \right) \times 100\%
\]

IC₅₀ was calculated by plotting a dose response graph of growth inhibition.

Lactate dehydrogenase (LDH) assay. Cells were seeded and grown separately in 96-well plate in medium containing 10% FBS and incubated for 24 h under 5% CO₂ at 37 °C. Then the cells were washed with PBS, 100 μL of each concentration of EE was added separately to the wells, and 100 μL of medium was added to the control well and incubated for 24 h. The cells were harvested, and the assay was carried out using the LDH kit (Thermo Fisher Sci. Ltd, USA). 100 μL of sample with working reagent was mixed and incubated for 1 min at 37 °C. The absorbance was measured at 340 nm and results of the assay were calculated according to the manufacturer’s instruction.

Western blot analysis. PANC-1 and MIAPaCa2 (2 × 10⁶) cells were treated separately with 500 μg/mL of EE for 24 h. After treatment, cells were lysed with radiolabeled immunoprecipitation assay buffer (Abcam, USA). The effect of treatment on the detection of certain cell cycle proteins such as p53, and on pro-apoptotic proteins such as caspase-3, caspase-9, and anti-apoptotic Bcl-2 were determined. Proteins were detected by incubation with the corresponding primary antibodies (Santa Cruz Biotechnology, USA: dilution 1:500). The following monoclonal antibodies were used: anti-caspase-9 (1-2): sc-56073 AC; anti-caspase-3 (E-8): sc–7272AC, anti-p53 (DO-1): sc–126, anti-Bcl-2 (C-2): sc–7382 AC, anti-actin(C4); sc–47778 AC, and HRP-conjugated secondary antibody. The blots were then detected using Luminol (Bio-Rad, USA). The intensity of each blots was measured by Image J.

Cell migration assay by scratch method. The migration assay was performed by the method of Lee et al. [12] with some modifications. Briefly, 5 × 10⁴ of PANC-1 cells per well was cultured in 6-well plate. After reaching 90% confluence, the center of the culture dishes was scratched with 100 μL pipette tip. Then the cells were washed frequently by using PBS and incubated with EE at concentration of 500 μg/mL for 24 h, image of the cells was taken. The relative migration rate was estimated by measuring the distance the cells migrated for 24 h as compared to the cells cultured without EE. The relative migration rate was calculated. Statistical analysis. GraphPad Prism 5 (GraphPad Software, Inc., USA) was applied for data analysis, and one-way analysis of variance (ANOVA) was done to compare the differences. The results were represented as means ± standard deviation/standard error from triplicate experiments done in a parallel, unless otherwise indicated. All figures were obtained from at least three independent experiments. P < 0.05 was considered to indicate a statistically significant difference.

RESULTS

Effects of EE on cell morphology. PANC-1 cells treated with 250 μg/mL EE lose their normal shape, become shrunken, and cell confluence is reduced. More round, shrunken, dead cells and cell debris were observed in cells treated with 500 μg/mL of EE (Fig. 1, a, b, c). Similar effects were obtained in MIAPaCa2 (Fig. 1, d, e, f).
Evaluation of apoptosis by DAPI staining. When DAPI-stained cells were examined under fluorescent microscope, nuclei of the cells of negative control appeared normal taking light blue color, and were round and homogeneous, while nuclei of cells treated with EE (250 or 500 μg/mL) were condensed and in few cases irregular and fragmented (Fig. 2, a–d). The percentage of apoptotic cells of PANC-1 and MIAPaCa2 cells treated with different concentrations of EE is given in Table 1. All the values are significantly higher than in control cells (p < 0.05) and dose dependence may be followed.

Antiproliferative effect of EE against PANC-1 and MIAPaCa2 cell lines. The data presented in Table 2 show that the proliferation of two cell lines was reduced gradually as the concentration of EE increased from 100 μg/mL to 750 μg/mL. Based on these data, IC_{50} values of EE against PANC-1 and MIAPaCa2 were calculated as 245 μg/mL and 332 μg/mL, respectively.

LDH assay. Fig. 3 demonstrates that LDH leakages from these two cell lines occur in dose-dependent manner. PANC-1 cells were more sensitive to EE (500 μg/mL) than MIAPaCa2 cells.

Expression of apoptosis-related proteins. Western blot analysis demonstrated the decreased expression of Bcl-2 protein in PANC-1 and MIAPaCa2 cells exposed to EE, while the expression of caspase-3 and caspase-9 as well as p53 increased in both cell lines (Fig. 4, a, b).

Migration inhibition of PANC-1 cells by wound healing/scratch assay. Cell migration is an important property of cancer cells. The effect of EE on cell migration was examined by a wound healing or scratch assay in vitro. Untreated PANC-1 cells filled the scratched space (Fig. 5, a) after the overnight culture (Fig. 5, c), while treatment with EE (500 μg/mL) reduced cell migration of PANC-1 cells evidenced by the wider open space left between two sides of the cells (Fig. 5, b). The relative cell migration rate inhibition calculated in comparison with control amounted to 80.12 ± 4.25% ($p < 0.05$).

DISCUSSION

In our experiments, EE of C. indica caused morphological changes of cells, induced apoptosis and inhibited proliferation of PANC-1, MIAPaCa-2 pancreatic cancer cell lines. Although this is the first work on the effect of C. indica extract in pancreatic cancer cells, mushroom extract from Cyathus striatus was recorded to inhibit the viability of other human pancreatic cell lines such as HPAF-II and PL45 in low concentration and with short exposure [9]. Cheng et al. [13] demonstrated that mixture of triterpenes extracted from Poria cocos and three pure triterpenes such as pachymic acid, dehydropachymic acid and polypropenetic acid C acted as anti-proliferative agents against four pancreatic cell lines (PANC-1, MIAPaCa-2, AsPC-1 and BxPC-3). Antiproliferative effect including ballooning (morphologic changes) by MMH01, a compound isolated from Antrodia cinnamomea against BXPC3 cell line was also shown [10], while Yu et al. [14] showed that antroquinonol, a ubiquinone derivative isolated from the same mushroom, inhibited cell proliferation of PANC-1 and AsPC-1 cells in a dose dependent manner. In this experiment in both cell lines morphological changes like rounding, shrinking, and membrane blebbing (bubbling) and the reduction of cell confluence were noted in 250 and 500 μg/mL of EE. Similar observation were recorded when HeLa cells were treated with 500 μg/mL/750 μg/mL of methanolic extract of Agaricus bisporus for 24 h at same conditions [15].

EE also caused leakage of LDH from treated cancer cells as evidenced from our LDH assay experiment. LDH levels measured by Sharvit et al. [9] suggested the lack of a necrotic effect of the extract of Cyathus striatus in cell line. In our previous work [8], ethanolic, methanolic and aqueous extracts of Calocybe indica was recorded as potent anti-cancerous substances against MCF-7 (breast cancer), MHH-ES1 (Ewing’s sarcoma) cells. On some other human cancer cell lines, Maiti et al. [16] reported antiproliferative action of C. indica. Similarly, the extract of this mushroom exhibited potent inhibitory effect against induced inflammation in the experimental mice model [17]. From the work of Rosendahl et al. [18], it was also found that polysaccharide K (PSK) from Coriolus

![Fig. 4. Relative levels of caspase-3, caspase-9, p53 and Bcl-2 in PANC-1 and MIAPaCa2 cells treated with EE (500 μg/mL) for 24 h (± SE bar at 5% level has been inserted) (a). Western blots of proteins (caspase-3, caspase-9, p53 and Bcl2) in PANC-1 and MIAPaCa2 cells treated with EE (500 μg/mL) for 24 h (b); control 1 & control 2 mean untreated PANC-1 & MIAPaCa2 cells, respectively](image)

![Fig. 5. Inhibition PANC-1 cell migration after treatment with 500 μg/mL of EE for 24 h; a — 0 h no migration; b — migration inhibition 24 h after treatment; c — 24 h, untreated cells or negative control, scratch portion fully packed by cells](image)
versicolor induced apoptosis in pancreatic cancer cells by increasing p21 WAF/Cip1 and antitumor growth effect of PSK on PANC-1, BxPC-3, AsPC-1 and MIAPaCa-2 were recorded by up-regulating cell cycle regulatory p21 WAF/Cip1 and pro-apoptotic protein Bax levels, as a result cell cycle arrest and induction of apoptosis occurred.

To identify possible molecular targets of EE from C. indica, we treated PANC-1 and MIAPaCa2 cells with EE, performed Western blotting analysis and observed that EE increased the protein products of pro-apoptotic genes such as caspase-3 and -9 while reduced the protein product of anti-apoptotic gene Bcl2. Another thing was that EE increased the level of p53 protein, which guards the cell from oncogenic action. In our migration experiment by scratch method, we observed that EE inhibited migration of PANC-1 cells by about 80%. Similarly, PSK inhibited invasion or migration of NOR-P1 pancreatic cell line by down-regulation of invasion-promoting factors such as TGF-β1 and MMPs (matrix metalloproteinase) as observed by Zhang et al. [19] in Matrigel-coated filters-invasion experiment.

Mushrooms are rich in natural bioactive compounds such as polysaccharides, terpenoids, proteins, peptides, polysaccharopeptoids etc. The commercialized polysaccharide from Phellinus linteus showed the effectiveness in postoperative adjuvant chemotherapy with surgical resection in pancreatic cancer patients [20]. The biologically active substrances of mushrooms responsible for immunomodulation and direct cytotoxicity toward cancer cell lines and the mechanisms of their antitumor action are worth of studying [21]. The present study provides new evidence that EE from mushroom C. indica inhibits growth and migration of pancreatic cancer cells.

FUNDING SOURCE

Authors acknowledge the financial support from the Department of Science & Technology and Biotechnology, GoWB, India [Grant No.840 (sanc)/ST/P/S&T/1G-1/2015)]. The funders have no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.

ACKNOWLEDGEMENT

Authors acknowledge Principal of Ramakrishna Mission Vivekananda Centenary College (Autonomous) for providing laboratory facilities.

CONTRIBUTION OF AUTHORS

SKG designed the experimental research work, investigated the whole work and wrote the manuscript. TS have done the experimental works, data collection, statistical analysis, and figure preparation.
